Congressional Stock Analysis

Do Congress Members Beat the Market?

Machine Learning on STOCK Act Disclosures · March 2026

Most Congressional Purchases Underperform the Market

Blindly copying congressional trades based on public disclosure dates **does not generate alpha**, the average politician underperforms their own risk-adjusted benchmark, making indiscriminate trade replication an inefficient strategy

15k
Total modeled trades

-0,5%
Median CAR

48.5%
Win rate

Holding period is calculated based on disclosed buy and sell date

How We Measure Performance: Cumulative Abnormal Return (CAR)

Cumulative Abnormal Return (CAR)	
Positive CAR (+) Compensated MORE for risk than CAPM predicts	Negative CAR (-) Compensated LESS, paid for risk that did not materialize

For each day, calculate the excess return relative to the stock's expected risk-adjusted return, then accumulate those daily excesses over the window.

Excess return
actual log return –
CAPM-expected log return

CAPM
E[R] = R, + B x (Rm - R,)
Beta (B) estimated from 756 trading days of close prices (min 60 days).

Window
Measured buy-to-sell (if <12 months) or a fixed 12-month window.
The clock starts the day AFTER the public filing date

Who Consistently Beats — and Loses to — the Market?

- Based on 101 politicians with ≥ 20 disclosed purchases
- evaluated based on CAR performance, amount of $ traded was not considered

Performance Over Time: Macro Events Drive Positive Rates

- 2020 Q2–Q3: surge in positive rate — COVID recovery bounce lifted most purchases
- 2022: sharp drop aligned with rate-hike drawdown across the market
- Volume spikes suggest increased trading activity around election cycles
- Positive rate rarely exceeds 60% — even in the best macro environments

# of trades Hit Rate

EDA: Median CAR Across Key Structural Variables

- Disclosure delay capped at 45 days by STOCK Act; 50d+ entries reflect late filers

Median CAR — Hit Rate

Committee Membership Shows Selective Advantage

- Orange = flag=1 (on committee / in role / company lobbied) · Blue = flag=0
- All 9 committee categories shown — previously only 5 were displayed
- Lobbied (90d): company had active lobbying disclosure in 90 days before filing date

Median Car — Hit Rate

Can an AI Model do better?

A machine learning filter **recovers a subset of trades with positive risk-adjusted returns**, suggesting that **informed selection** not blind replication is where the edge lies

2
Years of prediction data

Median Car

+0,5%	-1,95%
Optimal threshold	All trades

Hit Rate

51,5%	44,5%
Optimal threshold	All trades

Optimal strategy:
The model's value lies not in predicting every trade, but in knowing which ones to ignore, filtering congressional purchases down to the highest-confidence signals flips a losing strategy into a marginally profitable one

The Model: What Drives the Predictions?

Politician characteristics

Past politician performance

Lobbying activity

Intersections between traded companies and active lobbying

Committee Jurisdiction

Committee–industry jurisdictional overlap

Stock Characteristics

Conclusions & Caveats

Key Findings

- **Copying congressional trades blindly destroys value** — across the full test set, the median trade delivers -1.95% CAR with only a 44.6% win rate, meaning the average politician earns less than what their stocks' own systematic risk predicts

- **Lobbying activity and committee jurisdiction are the strongest structural signals** — whether a company was actively lobbying in the 90 days before filing is the single most important model feature, followed by committee oversight and direct industry-jurisdiction overlap

- **Selective filtering recovers the edge** — a machine learning model identifies a subset of trades with positive risk-adjusted returns, suggesting informed selection is where the alpha lies

Caveats

- **Single macro regime** — the test set covers Dec 2022 – Jan 2025 only; performance across different market environments (e.g. bull runs, rate cycles) is not validated out-of-sample

- **Execution constraints are not modelled** — no transaction costs, market impact, or liquidity limits are accounted for; real-world returns will be lower, particularly for less liquid tickers

- **Disclosed trades only** — STOCK Act compliance is imperfect; undisclosed or late-filed activity is not captured, meaning the dataset may systematically miss the most sensitive trades

Potential Data Enrichment (Lobbying Focus)

- **Lobbying depth** — currently only a binary 90-day presence flag; adding spend amount, trend direction, and which specific bills overlap with the politician's committee jurisdiction would sharpen the signal

- **Proximity signal** — days between the lobbying registration date and the trade's filing date; tighter proximity likely indicates more actionable information access

- **Revolving door** — identifying lobbyists who previously worked for the same politician or committee would flag trades with unusually direct information channels

Thank you

Methodology: How Key Signals Were Constructed

1 — Ticker ↔ Committee Matching

- Committee membership from timestamped YAML snapshots (unitedstates/congress-legislators on GitHub)
- For each trade, the snapshot closest in time to the Filed date is used
- Ensures membership reflects the politician's actual committees at trade time
- Committee codes truncated to 4 characters to normalize across snapshot formats
- Result: binary committee-category flags per trade (9 categories total)

2 — 3-Tier Committee–Industry Match

- Manual mapping in config/commette_industry_map.yaml: committee → sector → industry
- Tier 3 (Strong): committee has DIRECT JURISDICTION — controls budgets, contracts, or legislation
- Tier 2 (Medium): committee has OVERSIGHT — sets general rules, taxes, or compliance standards
- Tier 1 (Tangential): committee has INDIRECT impact — general legislative influence only
- Result: Industry match 1/2/3 binary flags per trade (1 = politician's committee matches stock's industry at that tier)

3 — Lobbying Signal

- Source: QuiverQuant lobbying disclosures API, downloaded per traded ticker
- lobbied_any_90d = 1 if the company had any active lobbying disclosure in 90 days before trade's Filed date
- Currently binary — lobbying spend amount and issue specificity are future enrichment candidates

APPENDIX

Dataset Overview

39,334	19,096	15,117	268
Total Records	Purchases	Modelled	Politicians

Metric	Value
Date range	2012-09-13 – 2026-01-30
Transaction types	Purchase / Sale / Sale (Full) / Sale (Partial) / Exchange
Unique tickers (purchases)	2,209
Parties	D / R / I
Chambers	Representatives / Senate
Target variable	realized_car_hybrid > 0 (binary)
CAR windows available	1m / 3m / 6m / 9m / 12m + realized
Train / test split	80% / 20% chronological
